

First challenge

Do you remember the Login App ? Recreate that application using only XIB views.

Second challenge (4)

Develop a shopping list application using only XIBs

The application will consist of two screens.

On the first screen:

- This screen will be designed to allow the user to select the items they wish to add to their shopping list.
- A list of items will be displayed with **buttons** containing representative images of typical supermarket products (create 10 different products).
- The buttons will change colours and images when selected/deselected.
- When **selected**, the buttons will have a green color and a checkmark image
- When **not selected** the buttons will have a blue color and an allusive image to the product or, if no image is found, use a shopping cart image.
- Once the user selects the items, they will be redirected to a second screen using another button that says "Let's Go Shopping"

On the second screen

- All selected items will be displayed in text format with a space and comma between them.
- This app does not support landscape mode, only portrait mode.

Hints:

- Tags, navigation controller, array (joined)
- You can create arrays of existing variables (can also be outlets) of the same type in order to iterate over them.
- See button "isSelected" property

Third challenge

Develop a music app using only XIBs

- The main screen should display the song title, artist name, and album artwork
- Include three essential **buttons**: back, play/pause, and forward.

- Add a **slider** control that moves in sync with the song “playback”.
- Its value should change according to the current song “playing” and the position.
- The right label represents time passed and the left label represents the remaining time of the song
- The play/pause **button** should toggle between both images depending on the current playback state.
- Implement the ability to advance to the next song and return to the previous one when the corresponding **buttons** are pressed. (Change duration, labels and images accordingly)
- A song has a name, a total duration, artist name, and album image
- This app does not support landscape mode, only portrait mode.

Hints:

- Using a structure to represent a song will make things easier
- Arrays, global variables

Extra challenge

Use a timer to mimic song playback: <https://www.hackingwithswift.com/articles/117/the-ultimate-guide-to-timer> . The pause/play button should update timer and the forward/back buttons should reset timer and change it's duration according to the new song.
